1 Introduction and Motivations

In the present work we aim to optimize the design of a coupled resonator waveguide QED to obtain flat transmission on a defined frequency range through apodization. In order to reach apodization we slightly modify the physical parameters of the resonators at both ends of the waveguide device so that the reflections cancel out the Fabry–Perot resonances at the resonant frequencies. This leads to a broadening of the characteristic peaks usually observed in transmission for coupled cavity arrays. Under optimal conditions, investigated by Chak et al. [1], we can exploit these broadenings to obtain flat transmission on a frequency band whose width depends on the number of resonators in the waveguide and on their coupling strength.

Apodized coupled resonator waveguides have been used for filtering applications as they operate as band-pass filters [2]. However, in recent years these devices have captivated more interest because of their possible use in slow light applications [3]. Slow light devices are based on the idea that the dispersion relation in periodic structures flattens at the transmission band edges. Since the group velocity is defined by the derivative of the dispersion relation, it is therefore small in regions where the dispersion relation goes flat, meaning that around the transmission band edges we can achieve both large transmission and low group velocity. These devices can be used to study non-Markovian dynamics i.e. dynamics of physical systems with memory of the past interactions [4].

Superconducting coplanar waveguide resonators have been also used to achieve strong coupling regime, paving the way for a multitude of new investigations [5, 6]. In addition, they represent an ideal platform to study quantum dynamics of systems interacting with a continuum of EM modes (multimode coupling).

2 Materials and Methods

In the following section I am going to provide a detailed account of the procedure that was followed in completing the project and the tools that were adopted. After a concise review of the theoretical background (subsection 2.1) I will present the softwares used for simulations (subsection 2.2) and the workflow (subsection 2.3) that guided the entire project, reporting all the relevant remarks and observations.

Note that in Appendix A is reported the python code used for the resonator waveguide design.

In the following section I am going to provide a detailed account of the procedure that was followed in completing the project and the tools that were adopted. After a concise review of the theoretical background (subsection 2.1) I will present the softwares used for simulations (subsection 2.2) and the workflow (subsection 2.3) that guided the entire project, reporting all the relevant remarks and observations.

Note that in Appendix A is reported the python code used for the resonator waveguide design.

2.1 Apodization in arrays of lumped-element resonators

We consider an array of $n = 8$ resonators, all featuring the same parameters, except for the first two and the last two.

Figure 1: *Coupled resonators waveguide schematic. ω_0 and ω'_0 are the resonators resonant frequencies while J and J' are the coupling strengths. γ is the energy decay rate of the edge sites*

We describe the resonators array using the tight-binding formalism, assuming periodic boundary conditions and considering only nearest-neighbor coupling. The corresponding n -site Hamiltonian is the following:

$$H = \begin{pmatrix} \omega'_0 + i\gamma & J' & 0 & & & & & \\ J' & \omega_0 & J & & & & & \\ 0 & J & \omega_0 & & & & & \\ & & & \dots & & & & \\ & & & & \omega_0 & J & 0 & \\ & & & & J & \omega_0 & J' & \\ & & & & 0 & J' & \omega'_0 + i\gamma & \end{pmatrix}$$

Where ω'_0 is the first (and last) resonator resonant frequency, J is the inter-site coupling, J' is the inter-site coupling between the first two (and the last two) resonators, γ is the energy decay rate of the edge sites due to the coupling to the measurement setup.

Figure 2: *Equivalent circuit representing the resonators waveguide on lumped element description. Note that we consider only nearest-neighbor coupling, secondary coupling has been neglected.*

We realize this Hamiltonian with a lumped-element resonator array coupled to transmission lines (Z_0 feedline input impedance).

The lumped-element resonator array parameters are related to the Hamiltonian parameters by:

$$J = \frac{C_c \omega_0}{2C_\Sigma} : \text{Inter-site coupling with total capacitance } C_\Sigma = C + 2C_c \text{ and resonant frequency } \omega_0 = \frac{1}{\sqrt{LC_\Sigma}}$$

$$J' = \frac{C_{c1} \omega'_0}{2C_{\Sigma'}} : \text{First two (and last two) resonators coupling with total capacitance } C_{\Sigma'} = C_k + 2C_2 + C_{c1} \text{ and resonant frequency } \omega'_0 = \frac{1}{\sqrt{LC_{\Sigma'}}}$$

$$\gamma = \frac{C_k^2 Z_0 \omega_0}{C_\Sigma^2 Z_r} : \text{Energy decay rate of the edge sites, with } Z_r = \sqrt{L/C_\Sigma}$$

In order to reach optimal apodization and obtain a flat passband in transmission, the conditions proposed by Chak and coworkers are the following [1]:

$$\begin{aligned} \omega'_0 &= \omega_0 \\ J' &= \sqrt{2}J \\ \gamma/2 &= 2J \sin(\psi) \end{aligned}$$

where $\psi = \pi/2$ (best matching at the middle of the band) or $\psi = \pi/4$ (best matching at the band edges). Considering the limit $C > C_k \gg C_{c1}, C_c$, we can meet these conditions with the following capacitances values:

$$\begin{aligned} C_{c1} &= \sqrt{2}C_c \\ C_k &= \sqrt{\frac{2C_c \sin(\psi)}{Z_0 \omega_0}} \\ C_1 &= C - (C_{c1} - C_c) \\ C_2 &= C - (C_{c1} + C_k - 2C_c) \end{aligned}$$

Where the first two conditions optimize the capacitances values to have the best result, while the last two ensure that $\omega'_0 = \omega_0$.

In [section 3](#) LTspice simulations have been used to prove that the values derived through these equations give indeed the best result: even with a small number of resonator, flat transmission is observed on a well defined frequency range proportional to the number of resonators.

2.2 Softwares and tools

In the current subsection I am going to briefly present the softwares used for simulations and the python library used to design the resonators waveguide.

LTspice and Cadence Microwave Office: circuit design softwares. High performance SPICE simulation software, schematic capture and waveform viewer with enhancements and models for easing the simulation of analog circuits.

Sonnet Software: EDA software solutions. Note that, despite Sonnet and LTspice have been both used to calculate the transmission spectrum, LTspice simulations are based on a circuit diagram that models the device while Sonnet simulates by numerically calculating Maxwell equations point by point on a 2-D representation of the real design. for high-frequency RF/MW electromagnetic analysis.

ANSYS: 3D electromagnetic (EM) simulation software for designing and simulating high-frequency electronic devices.

gdspsy library: Python module that allows the creation of GDSII stream files for micro and nano fabrication.

2.3 Workflow

The following subsection is dedicated to the presentation of the project workflow: I will provide an overview of the resonators waveguide design process, starting from the equations and finishing with the final waveguide design that will be fabricated.

2.3.1 Optimal capacitance values determination

The first step consisted in exploiting the equations, derived in [subsection 2.1](#), in order to find the best capacitance values for the resonator waveguide to obtain a flat band in transmission. Since we have more parameters than equations: 6 parameters to determine

$$C, C_c, C_{c1}, C_k, C_1, C_2$$

and only 4 equations,

$$C_{c1} = \sqrt{2}C_c$$

$$C_k = \sqrt{\frac{2C_c \sin(\psi)}{Z_0 w_0}}$$

$$C_1 = C - (C_{c1} - C_c)$$

$$C_2 = C - (C_{c1} + C_k - 2C_c)$$

we are free to assign arbitrary values to two of these parameters and successively derive the others. This comes really in handy when considering that, in circuit quantum electrodynamics, we have a narrow range of possible values for these capacitances due to the physical limits of the devices. We can therefore exploit these degrees of freedom to choose some convenient values, easy to realize.

Note that, in the present analysis, we are not considering L_0 and Z_0 since these parameters are fixed. Z_0 is the input feedline impedance for which we have only two possible values: 50Ω , and 500Ω which can be reached by tapering. On the other hand, we take L_0 as a fixed parameter ($L_0 = 38.8nH$) because we want a large inductance since it is needed for metamaterial waveguides [7, 8, 9], paving the way for future applications of the devices designed in this work. When increasing L_0 we induce a redshift in the resonators resonant frequency (defined as $w_0 = \frac{1}{\sqrt{LC_\Sigma}}$), therefore we cannot use inductance values larger than $\approx 40 nH$, otherwise the resonant peaks in transmission would appear in a range of the frequency spectrum we are not able to probe with the available lab instruments.

I started with $Z_0 = 50\Omega$ and I chose as starting point the following values:

$$C_c = 0.43 fF \quad , \quad C = 25 fF$$

where C_c represents the coupling capacitance between two neighbouring resonators in the waveguide and C is the coupling capacitance between a single resonator and ground, since these values have been already obtained for other devices in the past, therefore we knew they were achievable in practise.

Using Chak's equations we successively derived the values for the other parameters:

| C_c | C | C_k | C_{c1} | C_1 | C_2 |
|---------|-------|----------|----------|----------|---------|
| 0.43 fF | 25 fF | 19.63 fF | 0.61 fF | 24.82 fF | 5.62 fF |

Table 1: Values derived through Chak's equations starting from $C_c = 0.43 fF$, $C = 25 fF$

2.3.2 LTspice/Cadence simulations and design code

Once a proper choice of the starting parameters has been made, I simulated the transmission spectrum of the resonator waveguide using LTspice and Cadence Microwave Office. Simulations and parametric analysis have been used to confirm that the derived parameter values were indeed the ones giving the best results. As it is shown in [Figure 4](#), the closer the parameters are to the derived ones, the flatter is the band we observe in transmission.

After the simulations confirmed this starting set of values, I designed the first prototype of the device. In order to optimize and speed up the designed process I coded a program in Python, using the gdspy library, that prints out a fully customizable gds file of the resonators waveguide (the Python code is reported in [Appendix A](#))

Figure 3: *Transmission vs frequency for a standard coupled resonators waveguide not apodized (the parameters are set as: $C_c = C_{c1} = C_k$ and $C_1 = C_2 = C$).*

Figure 4: *Transmission spectrum for the apodized coupled resonators waveguide. The 4 traces in different colours represent 4 different set of values for the parameters C_k and C_{c1} . It is clear that the best result is achieved when using the values derived from Chak's equations: for $C_k = 19.63$ fF and $C_{c1} = 0.61$ fF a flat band is observed in transmission.*

2.3.3 Design optimization with $Z_0 = 50 \Omega$

The gds file has been then used to run a simulation on ANSYS in order to numerically calculate the capacitance matrix of this first design. The capacitance matrix provides, for each element of the waveguide (single resonators, ground, feedline capacitors), the coupling capacitances with respect to the other elements. The capacitance matrix

values, results of the simulation, have been then compared to the desired capacitance values derived from the equations. This first comparison allowed me to understand how far the starting design was from the optimal one I was looking for.

Figure 5: *First waveguide design: the ground piece between the first (last) and second (last second) resonators has been removed in order to reduce the capacitance to ground for the first resonator (C_2). Note that, for ANSYS simulations, the resonators must be separated from the ground (as you can see in this picture) so that they can be simulated as individual elements.*

| | C_c | C | C_k | C_{c1} | C_1 | C_2 |
|-------------------------|------------------|-----------------|------------------|------------------|-----------------|-------------------|
| Desired cap values | 0.43 fF | 25 fF | 19.63 fF | 0.61 fF | 24.82 fF | 5.62 fF |
| First design cap values | ≈ 1.5 fF | ≈ 17 fF | ≈ 5.5 fF | ≈ 2.5 fF | ≈ 15 fF | ≈ 14.5 fF |

Table 2: *Comparison between ANSYS simulation results and optimal capacitance values derived from Chak's equation*

The next phase has been characterized by a trial and error approach aimed to understand how different modifications in the physical structure of the device affected the capacitances values. To this purpose I have run several simulations on ANSYS changing each time a different parameter in the waveguide: for example capacitors thickness, capacitors length, distances between resonators and ground, and so on.

This analysis showed that, as expected, we can modify the coupling capacitance between two elements in the waveguide by:

- Increasing or decreasing the distance between the two elements. However, we cannot have a too large separation since we would have problems with the lithography process (used to fabricate the waveguide): first of all it would imply longer time and higher costs for the process, and it would also increase the probability of errors in the making.
- Modifying the thickness of the two elements. However, we cannot decrease it too much or an element which is supposed to be a capacitor will start behaving as an inductor in practise.
- Modifying the exposed surface between the two elements (see example in [Figure 6](#)).

Figure 6: Impact of the feedline capacitor length on C_k value. C_k represents the coupling capacitance between the first resonator and the feedline capacitor. Note that there are other waveguide features that strongly affect the value of C_k : the distance between the feedline capacitor and the resonator capacitor, the thickness of the capacitors.

After this initial study, I started modifying the waveguide design in order to achieve the optimal capacitance values. This step by step process gradually converged towards the optimal waveguide design: at each step the design was modified and simulated with ANSYS, then the simulations results, compared with the desired capacitance values, provided a feedback which suggested how to further modify the design.

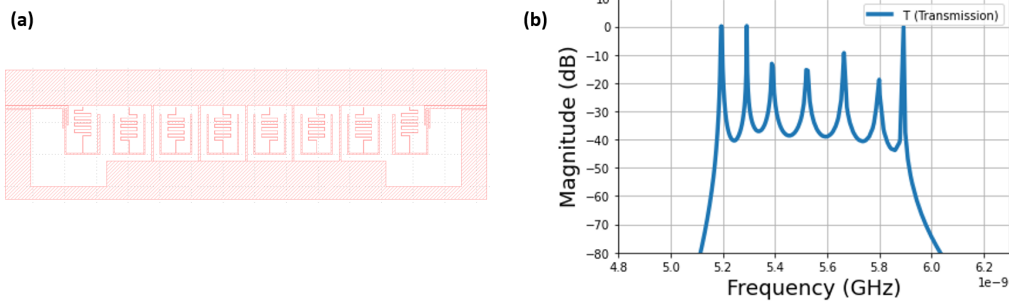

Figure 7: Sonnet simulation of the first waveguide design. The transmission spectrum shows several well defined peaks meaning that the waveguide is not apodized.

As shown Figure 5, the ground between the first and second resonators has been removed in order to decrease the capacitance to ground for the first resonator with respect to the others (indeed for the optimal capacitance values we have $C_2 \ll C$) and increase the capacitive coupling between the first two resonators (since $C_{c1} > C_c$).

During this design optimization process, together with ANSYS simulations, Sonnet simulations (Figure 7) were used to monitor the evolution of the transmission spectrum.

Thanks to this process I managed to design a waveguide that met the optimal parameters for C, C_c, C_{c1}, C_k, C_1 . However, the simulations showed that, for this kind of device, obtaining $C_2 = 5.62$ fF was not feasible (where C_2 is the coupling capacitance between the first/last resonators and ground). Even pushing the design to the limits the C_2 value calculated by ANSYS did not get smaller than $\approx 10 - 11$ fF (Figure 8).

I could not even lower the values of C_c and C_{c1} (where $C_{c1} = \sqrt{2}C_c$) to increase the optimal value of C_2 (where $C_2 = C - (C_{c1} + C_k - 2C_c)$) because they both have a very narrow range of achievable values ($\approx 0.1 - 3$ fF) and they were already quite small. If C_c and C_{c1} are too small, the waveguide does not work properly since these two values are proportional to the capacitive coupling between the resonators $J \propto C_c$ and $J' \propto C_{c1}$.

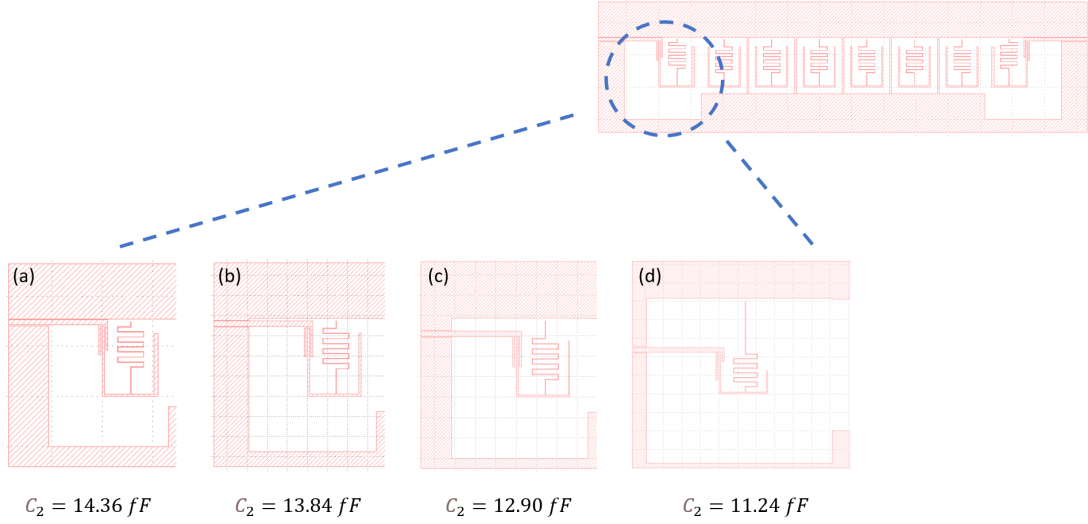

Figure 8: Attempts to decrease C_2 (first and last resonators capacitance to ground) in order to achieve the optimal value. In design (a) and (b) the separation between the first resonator and the ground is increased, in (c) and (d) the separation is increased and the first resonator capacitor thickness is reduced.

None of the proposed designs reach the optimal value for C_2 and it is not possible to increase further the distance from the ground since this would give problems during fabrication with the lithography process.

In order to overcome this problem, the solution was finding a new optimal capacitance values set. Therefore I exploited again the equations presented in [subsection 2.1](#), imposing $C_2 = 13$ fF this time. Note that C_2 has to be kept as small as possible because it is directly related to C value: following Chak's equations, the larger is C_2 the larger C is gonna be. Already for $C_2 \approx 15-20$ fF, C reaches values which are not achievable in practise for this kind of devices. Imposing $C_2 = 13$ fF allows to have achievable values for both C_2 and C .

Starting from $C_2 = 13$ fF and $C_c = 1$ fF, which ensures a good coupling between the resonators, I derived the new set of optimal capacitance values reported in [Table 3](#).

| C_c | C | C_k | C_{c1} | C_1 | C_2 |
|---------|----------|----------|----------|----------|----------|
| 1.00 fF | 48.00 fF | 35.29 fF | 1.41 fF | 47.58 fF | 13.30 fF |

Table 3: New set of optimal values derived starting from $C_2 = 13$ fF and $C_c = 1$ fF.

This new set contains all achievable capacitance values. However, in this case we have the resonators resonant frequencies:

$$f_0 = \frac{1}{\sqrt{LC_\Sigma}2\pi} \approx 3.6 \text{ GHz}$$

This is a problem for us because we cannot probe this range of frequencies with the instruments available in our lab.

Figure 9: ANSYS Capacitance matrix of the optimal design for the case $Z_0 = 50 \Omega$

The only remaining parameter that can be tuned is L_0 , even though reducing L_0 means giving up on high inductance to ground for our device. We have that:

$$L = L_\square \frac{l}{w}$$

Where L_\square is the inductance per square, l and w are the length and the width of the inductor wire. By shortening the inductor wire by almost half of its original length, I reduced L_0 from 38.8 nH to 20 nH, taking the resonators resonant frequencies to ≈ 5 GHz.

With this new set of parameters, adopting the same optimization procedure described before, I obtained the design shown in Figure 9. Note that the thickness of the resonators capacitors have been increased and the distance between the resonators and ground has been strongly decreased in order to achieve large C values. On the other hand, reaching a large C_k has been easy since the interdigitated feed line capacitor allows a good control over this parameter.

Note also that, despite the capacitance values calculated through ANSYS simulation (shown in Figure 9) are not close to the optimal values (shown in Table 3), this design is the one giving the best results for the case $Z_0 = 50 \Omega$.

2.3.4 Design optimization with $Z_0 = 500 \Omega$

We can achieve an input impedance of $Z_0 = 500 \Omega$ by tapering. This second case turned out to be much easier with respect to the first one since a larger value of Z_0 allows to reach apodization with lower capacitance values with respect to the previous case, easier to achieve, keeping at the same time a large L_0 ($L_0 = 38.8 \text{ nH}$).

Following the same process used for the $Z_0 = 50 \Omega$ case, I derived the set of optimal values reported in [Table 4](#).

| C_c | C | C_k | C_{c1} | C_1 | C_2 |
|---------|----------|---------|----------|----------|----------|
| 1.00 fF | 22.70 fF | 9.35 fF | 1.41 fF | 22.20 fF | 13.98 fF |

Table 4: New set of optimal values for the case $Z_0 = 500 \Omega$

Figure 10: ANSYS Capacitance matrix of the optimal design for the case $Z_0 = 500 \Omega$

Again, by a step by step design optimization, we obtained the design reported in [Figure 10](#) for this new case.

3 Results and Conclusions

In the following section will be presented the results and the conclusions of my work: I will show the two final designs, products of the optimization process presented in [subsection 2.3](#), and the relative transmission spectra.

3.1 Results

The optimal design for the case $Z_0 = 50 \Omega$ is reported in [Figure 11](#):

Figure 11: *Optimal design (a) and transmission spectrum (b) for the case $Z_0 = 50 \Omega$*

For the second case, $Z_0 = 500 \Omega$, the results are shown in [Figure 12](#):

Figure 12: *Optimal design (a) and transmission spectrum (b) for the case $Z_0 = 500 \Omega$*

In [Figure 11](#) and [Figure 12](#) we can observe that both the transmission spectra feature an asymmetric shape, a shoulder is visible on the right side of the bands. This asymmetry is inherited from the resonator waveguide transmission spectrum, which already shows this characteristic when not apodized (see [Figure 3](#)).

Another common characteristic is the presence of two residual peaks on the left side of the bands. We observe that these peaks are less pronounced in the second case ($Z_0 = 500 \Omega$), where we also have a larger frequency range with flat transmission: ≈ 0.3 GHz, compared to ≈ 0.15 GHz for the $Z_0 = 50 \Omega$ case. In order to mitigate these oscillations at the band edges we could use a larger number of resonators: with

more resonators we can increase the extent of the band and have flat transmission on larger frequency range.

In [Figure 13](#) are pictured the two different resonators designs for the two waveguides. In the first case ($Z_0 = 50 \Omega$) the capacitor has a wider and thicker bottom part in order to reach a larger value for the capacitance to ground $C = 48$ fF, while $C = 22.7$ fF in the case $Z_0 = 500 \Omega$. On the other hand, in order to compensate this larger capacitance value, the inductor wire is reduced by half in this case so that the resonators resonant frequencies (defined as $f_0 = \frac{1}{2\pi\sqrt{LC_\Sigma}}$, where C is the dominant factor in $C_\Sigma = C + 2C_c$) falls into the range 4.5 GHz - 6 GHz.

Figure 13: *Comparison between the two different resonators designs for the two waveguides*

3.2 Conclusions

Starting from the equations derived in [subsection 2.1](#), we successfully designed two coupled resonators waveguides, with different input impedances $Z_0 = 50 \Omega$ $Z_0 = 500 \Omega$, optimized to achieve apodization. Both devices clearly show flat transmission respectively in the frequency ranges 5.6 – 5.8 GHz ($Z_0 = 50 \Omega$ case) and 5 – 5.3 GHz ($Z_0 = 500 \Omega$ case), according to Sonnet simulations. These frequency ranges are optimal to study waveguide-SC qubits multimode coupling since superconducting qubits usually have frequencies in the range 4 – 8 GHz [\[10, 11, 12\]](#).

The waveguide designs have been derived through the process explained in [subsection 2.3](#). In order to optimize and speed up the design process we developed a Python program that prints out a fully customizable gds file of the resonators waveguide (see [Appendix A](#)).

7  the function is divided into 4 parts, each part is related to the
8  ↪ design of a specific component. In the end, all the
9  components are put together to crate the full WG. We have in order:
10
11     1) standard resonators pairs: the resonators pairs that form the
12     ↪ waveguide
13
14     2) first resonator (+ feedline capacitor): first resonator in the
15     ↪ waveguide and input feedline capacitor
16
17     3) last resonator: mirrored copy of the first resonator
18
19     4) ground design
20
21     NOTE: the various parts of the function create the negatives of the
22     ↪ components designs we need. At the end, the boolean "not" function
23     ↪ is used to subtract these negatives from a rectangle (which is the
24     ↪ ground) and we obtain the full WG
